**PROJECT SUMMARY/ABSTRACT** Genomic and epigenomic alterations that occur during cancer development affect all aspects of cellular function. However, a key challenge is to define these alterations and their functional consequences, and to understand how they are regulated in normal and tumor cells. DNA methylation is an important and reversible modification that plays important roles in gene regulation. Cancer cells are characterized by extensive genomic and epigenomic alterations, including abnormal DNA methylation patterns that regulate gene expression, genomic instability, and genome-wide changes in nucleosome positioning. However, the mechanisms of regulation of DNA methylation during carcinogenesis are largely unexplored. CTCF, a protein that binds to DNA and is required for normal development, is a member of the zinc finger family of proteins, and is a strong candidate for regulation of DNA methylation in cancer. CTCF binding is tightly controlled by multiple epigenetic mechanisms, including the DNA methylation-sensitive histone mark H3K4me3 and demethylation mediated by DNA hydroxymethylation (further referred to as 5hmC) and Tet enzymes. CTCF also interacts with Polycomb Repressive Complex 2 (PRC2), a component of the Polycomb Repressive Complexes that control H3K27me3, the histone mark associated with gene repression. We have identified a role for CTCF in controlling normal and tumor-specific DNA methylation by its ability to regulate both 5hmC and PRC2 activities at specific genes. Based on our preliminary data, we propose to test the hypothesis that CTCF maintains methylation patterns in a cell-type-specific and cancer-specific manner by establishing a balance between H3K4me3 and H3K27me3 in association with PRC2 and 5hmC. This hypothesis will be addressed by a combination of cellular, biochemical, and in vivo model approaches. Specific Aim 1 will examine the role of CTCF in the regulation of DNA methylation in cancer cells. We will determine the effects
